

Synthetic Research Fixture

This document is a synthetic integration-test fixture, not a real arXiv paper.

Abstract

We evaluate durable processing in a simulated set of 100 tasks.

Persisted checkpoints prevent repeated completed work after restart.

1. Method

The experiment compares replay with an in-memory baseline.

The synthetic workload contains 100 tasks and ten restart events.

Each task is assigned a stable identifier and a persisted result.

2. Results

The durable variant completed 100 tasks without losing recorded results.

The baseline repeated completed work after each restart.

No claim of exactly-once delivery to external systems is made.

3. Limitations

The experiment is synthetic and does not measure network partitions.

Results should not be generalized to production without additional tests.

4. Conclusion

Persistent checkpoints can support recovery under the stated test conditions.
